Google Photos Mistakenly Labels Black People 'Gorillas' BY CONOR DOUGHERTY JULY 1, 2015 7:01 PM # 41

| Email | Google continued to apologize Wednesday for a flaw in Google Photos, which was released to <u>great fanfare</u> in May, that led the new |
|-------|---|
| Share | application to mistakenly label photos of black people as "gorillas." |
| | The company said it had fixed the problem and was working to |
| Tweet | figure out exactly how it happened. |
| Save | "We're appalled and genuinely sorry that this happened," said a Google representative in an emailed statement. "We are taking |
| 11 | immediate action to prevent this type of result from appearing." |

From self-driving cars to photos, Google, like every technology company, is constantly releasing cutting-edge technologies with the understanding that problems will arise and that it will have to fix them as it goes. The idea is that you never know what problems might arise until you get the technologies in the hands of real-world users.

In the case of the Google Photos app — which uses a combination of advanced computer vision and machine learning techniques to help users collect, search and categorize photos — errors are easy to spot. When the app was unveiled at the company's annual developer show, executives went through carefully staged demonstrations to show how it can recognize landmarks like the Eiffel Tower and give users the ability to search their photos for people, places or things — even things as specific as a particular dog breed.

'A white mask worked better': why algorithms are not colour blind

By Ian Tucker

When Joy Buolamwini found that a robot recognised her face better when she wore a white mask, she knew a problem needed fixing

▲ Joy Buolamwini gives her TED talk on the bias of algorithms Photograph: TED

Joy Buolamwini is a graduate researcher at the MIT Media Lab and founder of the Algorithmic Justice League – an organisation that aims to challenge the biases in decision-making software. She grew up in Mississippi, gained a Rhodes scholarship, and she is also a Fulbright fellow, an Astronaut scholar and a Google Anita Borg scholar. Earlier this year she won a \$50,000 scholarship funded by the makers of the film *Hidden Figures* for her work fighting coded discrimination.

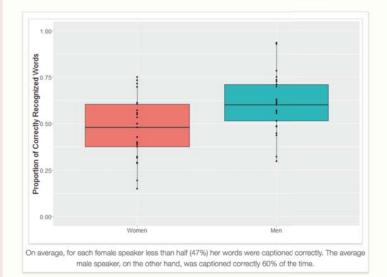

Google's Speech Recognition Has a Gender Bias

GOOGLE'S SPEECH RECOGNITION HAS A GENDER BIAS

Posted by Rachael Tatman in Uncategorized and tagged with computational linguistics, gender, linguistics, sociolinguistics, speech recognition, speech signal, speech technology

In my last post, I looked at how Google's automatic speech recognition worked with different dialects. To get this data, I hand-checked annotations more than 1500 words from fifty different accent tag videos.

Now, because I'm a sociolinguist and I know that it's important to stratify your samples, I made sure I had an equal number of male and female speakers for each dialect. And when I compared performance on male and female talkers, I found something deeply disturbing: YouTube's auto captions consistently performed better on male voices than female voice (t(47) = -2.7, p < 0.01.) (You can see my data and analysis here.)

It's not that there's a consistent but small effect size, either, 13% is a pretty big effect. The Cohen's d was 0.7 which means, in non-math-speak, that if you pick a random

Semantics derived automatically from language corpora contain human-like biases

Aylin Caliskan,^{1*} Joanna J. Bryson,^{1,2*} Arvind Narayanan^{1*}

Machine learning is a means to derive artificial intelligence by discovering patterns in existing data. Here, we show that applying machine learning to ordinary human language results in human-like semantic biases. We replicated a spectrum of known biases, as measured by the Implicit Association Test, using a widely used, purely statistical machine-learning model trained on a standard corpus of text from the World Wide Web. Our results indicate that text corpora contain recoverable and accurate imprints of our historic biases, whether morally neutral as toward insects or flowers, problematic as toward race or gender, or even simply veridical, reflecting the status quo distribution of gender with respect to careers or first names. Our methods hold promise for identifying and addressing sources of bias in culture, including technology.

e show that standard machine learning can acquire stereotyped biases from textual data that reflect everyday human culture. The general idea that text corpora capture semantics, including cultural stereotypes and empirical associations, has long been known in corpus linguistics (1, 2), but our findings add to this knowledge in three ways. First, we used word embeddings (3), a powerful tool to extract associations captured in text corpora; this method substantially amplifies the signal found in raw statistics. Second, our replication of documented human biases may yield tools and insights for studying prejudicial attitudes and behavior in humans. Third, since we performed our experiments on off-the-shelf machine learnnte Inrimarily the Clobal Vectore for

response times when subjects are asked to pair two concepts they find similar, in contrast to two concepts they find different. We developed our first method, the Word-Embedding Association Test (WEAT), a statistical test analogous to the IAT, and applied it to a widely used semantic representation of words in AI, termed word embeddings. Word embeddings represent each word as a vector in a vector space of about 300 dimensions, based on the textual context in which the word is found. We used the distance between a pair of vectors (more precisely, their cosine similarity score, a measure of correlation) as analogous to reaction time in the IAT. The WEAT compares these vectors for the same set of words used by the LAT. We describe the WEAT in more detail below.

Most closely related to this paper is conor

the reaction latencies of four pairings (flowers + pleasant, insects + unpleasant, flowers + unpleasant, and insects + pleasant). Greenwald et al. measured effect size in terms of Cohen's d, which is the difference between two means of log-transformed latencies in milliseconds, divided by the standard deviation. Conventional small, medium, and large values of d are 0.2, 0.5, and 0.8, respectively. With 32 participants, the IAT comparing flowers and insects resulted in an effect size of 1.35 ($P < 10^{-8}$). Applying our method, we observed the same expected association with an effect size of 1.50 $(P < 10^{-7})$. Similarly, we replicated Greenwald et al.'s finding (5) that musical instruments are significantly more pleasant than weapons (see Table 1). Notice that the word embeddings "know" these properties of flowers, insects, musical instruments, and weapons with no direct experience of the world and no representation of semantics other than the implicit metrics of words' co-occurrence

statistics with other nearby words. We then used the same technique to demonstrate that machine learning absorbs stereotyped biases as easily as any other. Greenwald *et al.* (5) found extreme effects of race as indicated simply by name. A bundle of names associated with being European American was found to be significantly more easily associated with pleasant than unpleasant terms, compared with a bundle of African-American names.

In replicating this result, we were forced to slightly alter the stimuli because some of the original African-American names did not occur in the corpus with sufficient frequency to be included. We therefore also deleted the same number of European-American names, chosen at random, to balance the number of elements in the sets of two concepts. Omissions and deletions are indicated in our list of keywords (see the supplementary materials).

In another widely publicized study, Bertrand and Mullainathan (7) sent nearly 5000 identical résumés in response to 1300 job advertisements, varging only the names of the candidates. They

Abstract

The blind application of machine learning runs therisk of amplifying biases present in data. Such a danger is facing us with word embedding, a popular framework to represent text data as vectors which has been used in many machine learning and natural language processing tasks. We show that even word embeddings trained on Google News articles exhibit female/male gender stereotypes to a disturbing extent. This raises concerns because their widespread use, as we describe, often tends to amplify these biases. Geometrically, gender bias is first shown to be captured by a direction in the word embedding. Second, gender neutral words are shown to be linearly separable from gender definition words in the word embedding. Using these properties, we provide a methodology for modifying an embedding to remove gender stereotypes, such as the association between the words receptionist and female, while maintaining desired associations such as between the words queen and *female*. Using crowd-worker evaluation as well as standard benchmarks, we empirically demonstrate that our algorithms significantly reduce gender bias in embeddings while preserving the its useful properties such as the ability to cluster related concepts and to solve analogy tasks. The resulting embeddings can be used in applications without amplifying gender bias.

ProPublica's Study of NorthPointe Software

Machine Bias

f 🎔 🖵 Don

There's software used across the country to predict future criminals. And it's biased against blacks.

> y Julia Angwin, Jeff Larson, Surya Mattu and Lauren Kirchner, ProPublica May 23, 2016

O N A SPRING AFTERNOON IN 2014, Brisha Borden was running late to pick up her god-sister from school when she spotted an unlocked kid's blue Huffy bicycle and a silver Razor scooter. Borden and a friend grabbed the bike and scooter and tried to ride them down the street in the Fort Lauderdale suburb of Coral Springs.

Just as the 18-year-old girls were realizing they were too big for the tiny conveyances which belonged to a 6-year-old boy — a woman came running after them saying, "That's my kid's stuff." Borden and her friend immediately dropped the bike and scooter and walked away.

But it was too late — a neighbor who witnessed the heist had already called the police. Borden and her friend were arrested and charged with burglary and petty theft for the items, which were valued at a total of \$80.

Compare their crime with a similar one: The previous summer, 41-year-old Vernon Prater was picked up for shoplifting \$86.35 worth of tools from a nearby Home Depot store.

Prediction Fails Differently for Black Defendants

(PRO)PUBLICA

| | WHITE | AFRICAN AMERICAN |
|---|-------|------------------|
| Labeled Higher Risk, But Didn't Re-Offend | 23.5% | 44.9% |
| Labeled Lower Risk, Yet Did Re-Offend | 47.7% | 28.0% |

Overall, Northpointe's assessment tool correctly predicts recidivism 61 percent of the time. But blacks are almost twice as likely as whites to be labeled a higher risk but not actually re-offend. It makes the opposite mistake among whites: They are much more likely than blacks to be labeled lower risk but go on to commit other crimes. (Source: ProPublica analysis of data from Broward County, Fla.)

Can an Algorithm Tell When Kids Are in Danger?

The New York Times Magazine

Child protective agencies are haunted when they fail to save kids. Pittsburgh officials believe a new data analysis program is helping them make better judgment calls.

Bias in computer systems (Friedman & Nissenbaum, 1996)

- Identified three sources of bias
 - 1. <u>Preexisting bias</u> from social institutions, practices, and attitudes
 - 2. <u>Technical bias</u> from technical constraints or considerations.
 - 3. <u>Emergent bias</u> from context of use
- "We conclude by suggesting that freedom from bias should be counted among the select set of criteria—including reliability, accuracy, and efficiency—according to which the quality of systems in use in society should be judged."

Figure from https://fairmlclass.github.io

How do computer scientists define fairness?

- Probabilistically
- Lots of parity (i.e., "fairness") definitions
 - Decisions should be in some sense probabilistically independent of sensitive features values (such as gender, race)
 - There are many possible senses

Confusion matrix

- Accuracy: How often is the classifier correct? (TP+TN)/total
- **Misclassification** (a.k.a. Error) **Rate**: How often is it wrong? (*FP*+*FN*)/total
- True Positive Rate (TPR, a.k.a. Sensitivity or Recall): When it's actually yes, how often does it predict yes? *TP/actual yes*
- False Positive Rate (FPR) : When it's actually no, how often does it predict yes? *FP/actual no*

| | Predicted: NO | Predicted: YES |
|-------------|---------------|----------------|
| Actual: NO | TN | FP |
| Actual: YES | FN | TP |

- Specificity (1 FPR) : When it's actually no, how often does it predict no? *TN/actual no*
- Precision (a.k.a. Positive Predictive Value): When it predicts yes, how often is it correct? *TP/predicted yes*
- Negative Predictive Value: When it predicts no, how often is it correct? *TN/predicted no*
- **Prevalence**: How often does the yes condition actually occur in our sample? *actual yes/total*

http://bit.ly/2xApsRz

http://bit.ly/2xApsRz

- Kleinberg, Mullainathan, Raghavan (2016)
- Chouldechova (2016)
- You can't have your cake and eat it too

Some definitions

- X contains features of an individual (e.g., medical records)
 - X incorporates all sorts of measurement biases
- A is a sensitive attribute (e.g., race, gender, ...)
 - A is often unknown, ill-defined, misreported, or inferred
- Y is the true outcome (a.k.a. the ground truth; e.g., whether patient has cancer)
- C is the machine learning algorithm that uses X and A to predict the value of Y (e.g., predict whether the patient has cancer)

https://fairmlclass.github.io

Some simplifying assumptions

- The sensitive attribute A divides the population into two groups a (e.g., whites) and b (e.g., non-whites)
- The machine learning algorithm C outputs 0 (e.g., predicts not cancer) or 1 (e.g., predicts cancer)
- The true outcome Y is 0 (e.g., not cancer) or 1 (e.g., cancer)

- Kleinberg, Mullainathan, Raghavan (2016), Chouldechova (2016)
- Assume differing base rates i.e., Pr_a (Y=1) ≠ Pr_b (Y=1) and an imperfect machine learning algorithm (C ≠ Y), then you can not simultaneously achieve
 - a) Precision parity: $Pr_a(Y=1|C=1) = Pr_b(Y=1|C=1)$.
 - b) True positive parity: $Pr_a(C=1|Y=1) = Pr_b(C=1|Y=1)$
 - c) False positive parity: $Pr_a(C=1|Y=0) = Pr_b(C=1|Y=0)$

- Kleinberg, Mullainathan, Raghavan (2016), Chouldechova (2016)
- Assume differing base rates i.e., Pr_a (Y=1) ≠ Pr_b (Y=1) and an imperfect machine learning algorithm (C ≠ Y), then you can not simultaneously achieve
 - a) Precision parity: $Pr_a(Y=1|C=1) = Pr_b(Y=1|C=1)$
 - b) True positive parity: $Pr_a(C=1|Y=1) = Pr_b(C=1|Y=1)$
 - c) False positive parity: $Pr_a(C=1|Y=0) = Pr_b(C=1|Y=0)$

"Equalized odds" -- Hardt, Price, Srebro (2016)

ProPublica and NorthPointe

- ProPublica's main charge was that black defendants experienced higher false positive rate
- Northpointe's main defense was that their risk assessment scores satisfy precision parity: Pr_a (Y=1|C=1) = Pr_b (Y=1|C=1)
- Due to the impossibility results, Northpointe's algorithm cannot satisfy "equalized odds"
 - Disproportionately high false positive rate for blacks
 - Disproportionately high false negative rate for whites

https://fairmlclass.github.io

Group vs. individual fairness

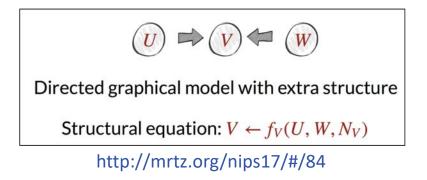

- Fairness through awareness by Dwork, Hardt, Pitassi, Reingold, Zemel (2012)
- "People who are similar w.r.t. a specific (classification) task should be treated similarity."
- Does not get around the impossibility results
- Assuming you have equal base rates, treating everyone equally is a good move

Solutions considered from the machine learning side so far (1/2)

- Preprocessing or "massaging" the data to make it less biased
- Learning fair representations: encode data while obfuscating sensitive attributes
- Penalize the algorithm to encourage it to learn fairly
 - During training (e.g., through regularization or constraints) or as a postprocessing step
- Allow the sensitive attributes to be used during training, but do not make them available to the model during inference time

Solutions considered from the machine learning side so far (2/2)

- Causal modeling
 - "Everything else being equal" cases
 - Findings depend strongly on model and assumptions
- Excellent tutorial at NIPS 2017 by Solon Barocas and Moritz Hardt
 - Slides: http://mrtz.org/nips17/
 - Video: https://vimeo.com/248490141

Solutions considered from the policy side

- Regulations
- The EU has General Data Protections Regulation (GDPR) data laws going into effect on May 25, 2018
- These laws grant users a "right to explanation" of any automated decision-making as applied to them
- Wikipedia entry: http://bit.ly/1lmrNJz

Just machine learning in an unjust world?

- Racist/sexist humans e.g., biased judges
- Stupid algorithms are already in use e.g., three-strikes laws, mandatory minimum sentencing
 - They don't take enough empirical data into account
 - Machine learning can help here
 - Personalization, context-awareness, ...

Where do we go from here?

"Computers may be intelligent, but they are not wise. Everything they know, we taught them, and we taught them our biases. They are not going to un-learn them without transparency and corrective action by humans." -- Ellora Thadaney Israni

https://www.nytimes.com/2017/10/26/opinion/algorithm-compas-sentencing-bias.html

An interdisciplinary call for action

- You can't have <u>all</u> the different kinds of fairness that you might want
 - Recall the impossibility results
- We need to work together across disciplines to reach agreement in terms of which kinds of "fairness" we want to optimize
 - Fairness based on explanation?
 - Fairness based on placement?
 - Fairness based on complex networks?

- How should we represent implicit vs. explicit bias?
 - Is explicit bias represented as rules?
 - Is implicit bias a set of examples from which to draw conclusions?

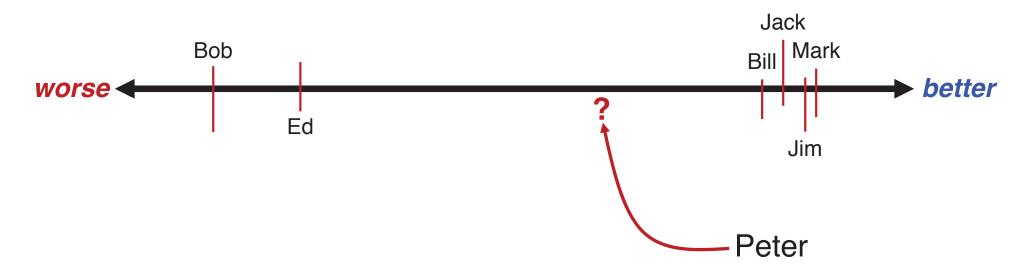

- How should we represent implicit vs. explicit bias?
 - Is explicit bias represented as rules?
 - Is implicit bias a set of examples from which to draw conclusions?
- How should we capture intent in machine learning?
 - Our anti-discrimination laws incentivize the framing of cases in terms of intent

- How should we represent implicit vs. explicit bias?
 - Is explicit bias represented as rules?
 - Is implicit bias a set of examples from which to draw conclusions?
- How should we capture intent in machine learning?
 - Our anti-discrimination laws incentivize the framing of cases in terms of intent
- Are data-driven approaches ideal in all cases?
 - Data are the results of cases meeting the laws/guidelines and subject matter experts

- What should the objective function be?
 - Sometimes there are multiple objective functions that are at odds with each other – e.g., child protective services
- Do we care about harm or do we care about benefit?
- Do we care about treatment or do we care about impact?
- Can we create a decision procedure that helps formulate objective functions?

Learning to place

Given a sequence of ordered cases, where should we place a new case?

Thank you!
